Narrative Report on Ideaspace:#Technopreneur Bootca@CentralLuzon

As a requirement of the fifth year BSECE students to the subjects and Field Trips and Seminars (FTS), I participated in Ideaspace:#Technopreneur Bootcamp@CentralLuzon and this seminar is all about on how you could be a great engineer, on how you could be one of those successful entrepreneurs who used their creative thinking into creating something out of nothing, it was conducted on July 13, 2013 at the Angeles University Foundation, Angeles City, Pampanga.

The seminar was started by prayer and then followed by singing of the national anthem conducted by the Organizer of the seminar. The opening remark was then given also by the organizer of the seminar.

After that, the first speaker was introduced to the students and he spoke about how he got to the top, he said that you need to persevere if you want to succeed. Another speaker was introduced after a few hours, this speaker is already a CEO at just the age of 21, he started his company from scratch, he has no budget, because he only study in a public school, but now he already earned millions and was personally introduced to Manny Pangilinan of Smart Communications. Some interesting questions were raised by the students and were answered by the speakers. The seminar was fun and very educational. After the lecture, a token of appreciation was awarded to speaker.

The students had an hour break for lunch from 12:00pm to 1:00pm.

To begin the second part of the seminar, the speaker also provided the students some keenness on improving their projects. The Speaker, likewise, was awarded with token of appreciation after his lectures.

The Organizer of the seminar gave the closing remark to officially end the program.

The certificate of attendance for the students was distributed the day after tomorrow.

Narrative Report BASIC PIC MICROCONTROLLERS SEMINAR

Read Full PDF PackageRead Full PDF PackageThis PaperA short summary of this paperAs related to this paperReadPDF Pack It is the technology provide virtual environment by the touch sensation or the mechanical motion of the user. These technologies are used in the remote control machines and devices. This system is the combinations of tactile information and kinesthetic information collected from the sensors that are connected to the user skin. This technique is used by the physicians to locate the hidden information collected from the sensors that are connected at the joints. These devices are broadly classified in to the following categories: - Virtual reality - Feedback devices (stationary devices, wearable device, locomotion interfaces) - Tactile display devices - Phantom - Cyber gloves This device consists of two parts; human part and the machine part. Human parts control the motion of the device with the sensors. And the machine part created pressure from the behind of the hand to stimulate the contact with virtual machine in the form of some sensation on the body. This technology is used in the gaming world for creating real life games. They use them in training and for safety purpose also. They use them in training and for safety purpose also. They use them in training and for safety purpose also. simulators. This is the advanced technology which enables us to feel the object without even touching them in real. But these devices are very rare and very costly for the use. this will be the great boon for the future applications. Download Seminar Report and Documentation on Haptic technology & Management Gandhinagar Campus, Rushikonda, visakhapatnam. 530045. Web site: www.Gitam.edu, PAPER PRESENTATION ON HAPTIC TECHNOLOGY BY Neha Jha & D. Naga sivanath 34 EIE, GITAM, Vishakhapatnam. 1 2. ABSTRACT "HAPTICS"-- a technology that adds the sense of touch to virtual environment. Haptic interfaces allow the user to feel as well as to see virtual objects on a computer, and so we can give an illusion of touching surfaces, shaping virtual clay or moving objects around. The sensation of touch is the brain's most effective learning mechanism --more effective than seeing or hearing—which is why the new technology holds so much promise as a teaching tool. Haptic technology is like exploring the virtual world with a stick. If you push the stick into a virtual balloon push back .The computer communicates sensations through a haptic interface -a stick, scalpel, racket or pen that is connected to a force-exerting motors. With this technology we can now sit down at a computer terminal and touch objects that exist only in the "mind" of the computer. By using special input/output devices (joysticks, data gloves, or other devices), users can receive feedback from computer applications in the hand or other parts of the body. In combination with a visual display, haptics technology can be used to train people for tasks requiring hand-eye coordination, such as surgery and space ship maneuvers. In this paper we explicate how sensors and actuators are used for tracking the position and movement of the haptic device moved by the operator. We mention the different types of force rendering algorithms. Then, we move on to a few applications of Haptic Technology. Finally we conclude by mentioning a few future developments. 2 3. Introduction 1 What is Haptics? Haptics refers to sensing and manipulation through touch. The history of the haptic interface dates back to the 1950s, when a master-slave system was proposed by Goertz (1952). Haptic interfaces were established out of the field of tele-operation, which was then employed in the remote manipulation of radioactive materials. The ultimate goal of the tele-operation system was "transparency". That is, an user interacting with the master device in a master-slave pair should not be able to distinguish between using the master controller and manipulating the actual tool itself. Early haptic interface systems were therefore developed purely for telerobotic application incorporating visual, auditory, and haptic feedback. 1 • Simulation engine: Responsible for computing the virtual environment's behavior over time. 1 • Visual, auditory, and haptic rendering algorithms: Compute the virtual environment's graphic, sound, and force responses toward the user. • Transducers: Convert visual, audio, and force signals from the computer into a form the operator can perceive. 1 • Rendering: Process by which desired sensory stimuli are imposed on the user to convey information about a virtual haptic object, 3.4. The human operator typically holds or wears the haptic interface device and perceives audiovisual feedback from audio (computer speakers, headphones, and so on) and visual displays (a computer speakers, headphones, and so on) and visual displays (a computer speakers, headphones, and so on) and visual displays (a computer speakers, headphones, and so on) and visual displays (a computer speakers, headphones, and so on) and visual displays (a computer speakers, headphones, and so on) and visual displays (a computer speakers, headphones, and so on) and visual displays (a computer speakers, headphones, and so on) and visual displays (a computer speakers, headphones, and so on) and visual displays (a computer speakers, headphones, and so on) and visual displays (a computer speakers, headphones, and so on) and visual displays (a computer speakers, headphones, and so on) and visual displays (a computer speakers, headphones, and so on) and visual displays (a computer speakers, headphones, and so on) and visual displays (a computer speakers, headphones, and so on) and visual displays (a computer speakers, headphones, and so on) and visual displays (a computer speakers, headphones, and so on) and visual displays (a computer speakers, headphones, and so on) and visual displays (a computer speakers, headphones, and so on) and visual displays (a computer speakers, headphones, and so on) and visual displays (a computer speakers, headphones, headphon and energy flow (from the simulation engine towards the user) whereas, the haptic modality exchanges information and energy in two directions, from and toward the user. This bi directionality is often referred to as the single most important feature of the haptic interaction modality. System architecture for haptic rendering: An avatar is the virtual representation of the haptic interface through which the user physically interacts with the virtual environment. Haptic rendering algorithms compute the correct interaction forces between the haptic interface representation inside the virtual environment. Haptic rendering algorithms ensure that the haptic device correctly renders such forces on the human operator. 1.) Collision-detection algorithms detect collisions (penetrations, indentations, contact area, and so on) have occurred. 2.) Forceresponse algorithms compute the interaction force between avatars and virtual objects when a collision is detected. This force approximates as closely as possible the contact forces that would normally arise during contact between real objects. 4 5. Hardware limitations prevent haptic devices from applying the exact force computed by the forceresponse algorithms to the user. 3.) Control algorithms command the haptic device in such a way that minimizes the error between ideal and applicable forces. The discrete-time nature of the haptic rendering algorithms often makes this difficult. The force response algorithms of the user. 3.) commanded to the haptic device. Existing haptic rendering techniques are currently based upon two main principles: "point- interactions, a single point, usually the distal point of a probe, thimble or stylus employed for direct interaction with the user, is employed in the simulation of collisions. The point penetrates the virtual objects, and the depth of indentation is calculated between the current point and a point on the surface of the object. Forces are then generated according to physical models, such as spring stiffness or a spring-damper model. In ray-based rendering, the user interface mechanism, for example, a probe, is modeled in the virtual environment. as a finite ray. Orientation is thus taken into account, and collisions are determined between the simulated probe and virtual objects. Computing contact-response forces: Humans perceive contact with real objects through sensors (mechanoreceptors) located in their skin, joints, tendons, and muscles. We make a simple distinction between the information refers to the spatial distribution of pressure, or more generally, tractions, across the contact area. To handle flexible materials like fabric and paper, we sense the pressure variation across the fingertip. Tactile sensing is also the basis of complex perceptual tasks like medical palpation, where physicians locate hidden anatomical structures and evaluate tissue properties using their hands. 2. Kinesthetic information refers to the information acquired through the sensors in the joints. Interaction forces are normally perceived through a combination of these two. To provide a haptic simulation experience, systems are designed to recreate the contact forces are normally perceived through the sensors in the joints. Interaction forces are normally perceived through a combination of these two. To provide a haptic simulation experience, systems are designed to recreate the contact forces are normally perceived through a combination of these two. To provide a haptic simulation experience, systems are designed to recreate the contact forces are normally perceived through a combination of these two. 2. Forces due to object surface properties, such as texture and friction. Geometry-dependent force-rendering algorithms are also grouped by the number of Degrees-offreedom (DOF) necessary to describe the interaction force being rendered. Surface property-dependent force-rendering algorithms: All real surfaces contain tiny irregularities or indentations. Higher accuracy, however, sacrifices speed, a critical factor in real-time applications. Any choice of modeling technique must consider this tradeoff. Keeping this trade-off in mind, researchers have developed more accurate haptic-rendering algorithms for friction. In computer graphics, texture mapping adds realism to computer graphics. forces have been computed, they must be applied to the user. Limitations of haptic device technology, however, have sometimes made applying the force's exact value as computed by force-rendering algorithms impossible. They are as follows: 1 • Haptic interfaces can only exert forces with limited magnitude and not equally well in all directions 2 • Haptic devices aren't ideal force transducers. An ideal haptic device would render zero impedance when simulating movement in free space, and any finite impedance when simulating contact with an object featuring such impedance when simulating movement in free space, and any finite impedance when simulating movement in free space, and any finite impedance when simulating movement in free space, and any finite impedance when simulating movement in free space, and any finite impedance when simulating movement in free space, and any finite impedance when simulating movement in free space, and any finite impedance when simulating movement in free space, and any finite impedance when simulating movement in free space, and any finite impedance when simulating movement in free space, and any finite impedance when simulating movement in free space, and any finite impedance when simulating movement in free space, and any finite impedance when simulating movement in free space, and any finite impedance when simulating movement in free space, and any finite impedance when simulating movement in free space, and any finite impedance when simulating movement in free space, and any finite impedance when simulating movement in free space, and any finite impedance when simulating movement in free space, and any finite impedance when simulating movement in free space, and any finite impedance when simulating movement in free space, and any finite impedance when simulating movement in free space, and any finite impedance when simulating movement in free space, and any finite impedance when simulating movement in free space, and any finite impedance when simulating movement in free space, and any finite impedance when simulating movement in free space, and any finite impedance when simulating movement in free space, and any finite impedance when simulating movement in free space, and any finite impedance when simulating movement in free space, and any finite impedance when simulating movement in free space, and any finite impedance ideal. 3 • A third issue is that haptic-rendering algorithms operate in discrete time whereas users operate in continuous time. 6 7. Finally, haptic device position sensors have finite resolution. Consequently, attempting to determine where and when contact occurs always results in a quantization error. It can create stability problems. All of these issues can limit a haptic application's realism. High servo rates (or low servo rate periods) are a key issue for stable haptic devices: 1 • Devices that allow users to touch and manipulate 3-dimentional virtual objects. 2 • Devices that allow users to "feel" textures of 2-dementional objects. Another distinction between haptic interface devices is their intrinsic mechanical behavior. Impedance haptic devices simulate mechanical impedance-type architectures are most common. Admittance haptic devices simulate mechanical admittance—they read force and send position. Admittance-based devices are generally used for applications requiring high forces in a large workspace. LOGITECH WINGMAN FORCE FEEDBACK MOUSE It is attached to a base that replaces the mouse mat and contains the motors used to provide forces back to the user. Interface use is to aid computer users who are blind or visually disabled; or who are tactile/Kinesthetic learners by providing a slight resistance at the edges of windows and buttons so that the user can "feel" the Graphical User Interface (GUI). This technology can also provide resistance to textures in computer images, which enables computer users to "feel" pictures such as maps and drawings. 7 8. PHANTOM: The PHANTOM provides single point, 3D force- feedback to the user via a stylus (or thimble) attached to a moveable arm. The position of the stylus point/fingertip is tracked, and resistive force is applied to it when the device comes into 'contact' with the virtual model, providing accurate, ground referenced force feedback. The physical working space is determined by the extent of the arm, and a number of models are available to suit different user requirements. The phantom system is controlled by three direct current (DC) motors that have sensors and encoders attached to them. The number of motors corresponds to the number of degrees of freedom a particular phantom system has, although most systems produced have 3 motors. The encoders track the motors track gimbals which attaches to the thimble or stylus. A gimbal is a device that permits a body freedom of motion in any direction or suspends it so that it will remain level at all times. Used in surgical simulations and movement of the fingers and wrist. The basic Cyber Glove system includes one CyberGlove, its instrumentation unit, serial cable to connect to your host computer, and an executable version of VirtualHand graphic hand model display and calibration software developer to provide the CyberGlove wearer with additional input/output capability. With the appropriate software, it can be used to interact with systems using hand gestures, and when combined with a tracking device to determine the hand's position in space, it can be used to manipulate virtual objects. Cyber Grasp is a full hand forcefeedback exo skeletal device, which is worn over the CyberGlove. CyberGrasp consists of a 8 9. lightweight mechanical assembly, or exoskeleton, that fits over a motion capture glove. About 20 flexible semiconductor sensors are sewn into the fabric of the glove measure hand, wrist and finger movement. The sensors send their readings to a computer that displays a virtual hand mimicking the real hand's flexes, tilts, dips, waves and swivels. The same program that moves the virtual hand on the screen also directs machinery that exerts palpable forces on the real hand, creating the illusion of touching and grasping. A special computer called a force control unit calculates how much the exoskeleton assembly should resist movement of the real hand in order to simulate the onscreen action. Each of five actuator motors turns a spool that rolls or unrolls a cable. The cable conveys the resulting pushes or pulls to a finger via the exoskeleton. Applications Medical training applications: Such training systems use the Phantom's force display capabilities to let medical trainees experience and learn the subtle and complex physical interactions needed to become skillful in their art. 9 10. A computer based teaching tool has been developed using haptic technology to train veterinary students to examine the bovine reproductive tract, simulating rectal palpation. The student receives touch feedback from a haptic device while palpating virtual objects. The teacher can visualize the student's actions on a screen and give training and guidance. Collision Detection: Onlision Detection on a screen and give training and guidance. Collision Detection is a fundamental problem in computer animation, physically-based modeling, geometric modeling, and robotics. In these fields, it is often necessary to compute distances between objects or find intersection regions. In particular, I have investigated the computation of global and local penetration detection. These proximity queries have been applied to haptic rendering and rigid body dynamics simulation. Minimally Invasive Surgery: The main goal of this project is to measure forces and torques exerted by the surgeon during minimally-invasive surgery in order to optimize haptic feedback. A standard da Vinci tool affixed with a 6 DOF force/torque transducer will be used to perform basic surgical procedures and the forces applied by the tool will be recorded and analyzed. This will help determine in which degrees of freedom forces are most commonly applied. 10 11. Stroke patients: Stroke patients who face months of tedious rehabilitation to regain the use of impaired limbs may benefit from new haptics systems -- interfaces that add the sense of touch to virtual computer environments -- in development at the University of Southern California's Integrated Media Systems Center (IMSC). The new systems, being designed by an interdisciplinary team of researchers from the Viterbi School of Engineering and the Annenberg School for Communication, are challenging stroke patients to grasp, pinch, squeeze, throw and push their way to recovery. Prostate Cancer: 11 12. Prostate cancer is the third leading cause of death among American men, resulting in approximately 31,000 deaths annually. A common treatment method is to insert needles into the prostate to distribute radioactive seeds, destroying the cancerous tissue. This procedure is known as brachytherapy. The prostate itself and the surrounding organs are all soft tissue. Tissue deformation makes it difficult to distribute the seeds as planned. In our research we have developed a device to minimize this deformation, improving brachytherapy by increasing the seed distribute the seeds as planned. In our research we have developed a device to minimize this deformation, improving brachytherapy by increasing the seed distribute the seeds as planned. In our research we have developed a device to minimize this deformation, improving brachytherapy by increasing the seed distribute the seeds as planned. In our research we have developed a device to minimize this deformation, improving brachytherapy by increasing the seed distribute the seeds as planned. In our research we have developed a device to minimize this deformation accuracy. holding them at the mouth of the laser/aspiration probe using vacuum and firing the laser to fragment them for aspiration. However, several surgeons have developed by Dr. Dodick himself, involves inserting two Dodick-Kallman Choppers under the anterior capsulotomy, 180? apart and out to the equator of the lens. The surgeon rotates the choppers downward and draws them towards each half. Using the irrigation probe to support the segments during removal is helpful. 12 13. Settings: Aspiration: 275 to 300 mmHg; Air infusion: 80 to 100 mmHg; Laser pulses: 1 Hz. Wehner backcracking. This technique, developed by Wolfram Wehner, M.D., uses the Wehner Spoon, an irrigating handpiece that resembles a shovel at the tip. The surgeon lifts the nucleus using the laser/aspiration probe, inserts the Wehner spoon underneath, and uses the two probes to backcrack the nucleus. The Wehner spoon provides support during removal of the lens segments. Settings: Aspiration: 275 mmHg; Laser pulses: 3 Hz. Intelligent Machines is an inter-departmental inter-faculty research group which was formed to facilitate and promote research on intelligent systems. Intelligent systems and machines are capable of adapting their environment, making decisions and plans, and then carrying out those plans using physical actions. The mission of CIM is to excel in the field of intelligent machines, stressing basic research, technology development, and education. CIM seeks to advance the state of knowledge in such domains as robotics, automation, artificial intelligence, computer vision, systems and control theory, and speech recognition. This is being achieved by collaborative efforts involving researchers with very different interests - CIM faculty and students come from the School of Computer Science, Department of Electrical and Computer Engineering, and the Department of Mechanical Engineering. It is this diversity of interests along with the spirit of collaboration which forms the driving force behind this dynamic research community. 13 14. Tactile slip display: Human fingers are able to manipulate delicate objects without either dropping or breaking them, but lose this ability to a certain degree when using a tele-operated system. One reason for this is that human fingers are equipped with sensors that tell us when our fingerprints at the edge of the contact area start to come off the object. While several other researchers have built synthetic skins for their robot fingers that work in a similar way to human fingerprints, a tactile haptic device is needed to display these sensations to a human using a tele-operated system. For this purpose we have designed the 2 degree of freedom Haptic Slip Display. We have conducted psychophysical experiments validating the device design and demonstrating that it can improve user performance in a delicate manipulation task in a virtual environment. Gaming technology: Flight Simulations: Motors and actuators push, pull, and shake the flight yoke, throttle, rudder pedals, and cockpit shell, replicating all the tactile and kinesthetic cues of real flight. Some examples of the simulator's haptic capabilities include resistance in the yoke from pulling out of a hard dive, the shaking caused by stalls, and the bumps felt when rolling down concrete runway. These flight simulator can immediately start flying a real commercial airliner. Today, all major video consoles have built-in tactile feedback capability. Various sports games, for example, let you feel bone-crushing tackles or the different vibrations caused by skateboarding over plywood, asphalt, and concrete. Altogether, more than 500 games use force feedback, and more than 20 peripheral manufacturers now market in excess of 100 haptics hardware products for gaming. Mobile Phones: Samsung has made a phone, which vibrates, differently for differe technology), which uses a small wheel on the console to give haptic feedback so the driver can control the peripherals like stereo, heating, navigation system etc. through menus on a video screen. The firm introduced haptic technology for the X-by-Wire system and was showcased at the Alps Show 2005 in Tokyo. The system consisted of a "cockpit" with steering, a gearshift lever and pedals that embed haptic technology, and a remote-control car. Visitors could control ar emote control car by operating the screen in front of the cockpit, which is projected via a camera equipped on the remote control car. Robot Control: For navigation in dynamic environments or at high speeds, it is often desirable to provide a sensor-based collision avoidance scheme on-board the robot to guarantee safe navigation. Without such a collision avoidance scheme, it would be difficult for the (remote) operator to prevent the robot from colliding with obstacles. This is primarily due to (1) limited information from the robots' sensors, such as images within a restricted viewing angle without depth information, which is insufficient for the user's full perception of the environment in which the robot. Experiments on robot control using haptic devices have shown the effectiveness of haptic feedback in a mobile robot tele-operation system for safe navigation in a shared autonomy scenario. Future Enhancements: Force Feedback Provided In Web Pages: This underlying technology automatically assigns "generic touch sensations" to common Web page objects, such as hyperlinks, buttons, and menus. Virtual Brailee Display: 15 16. The Virtual Brailee Display (VBD) project was created to investigate the possibility of using the lateral skin stretch technology of the STReSS tactile display for Braille. The project was initially conducted at VisuAide inc. and is now being continued in McGill's Haptics Laboratory. Haptic torch for the blind: The device, housed in a torch, detects the distance to objects, while a turning dial on which the user puts his thumb indicates the changing distance to an object. The pictured device was tested and found to be a useful tool. CONCLUSION: Haptic is the future for online computing and e-commerce, it will enhance the shopper experience and help online shopper to feel the merchandise without leave their home. Because of the increasing applications of haptics, the cost of the haptic devices will drop in future. This will be one of the major reasons for commercializing haptics. With many new haptic devices will drop in future. This will be one of the major reasons for commercializing haptics.
